

CYB 210 Project Two Scenario One

Scenario

You are a junior security analyst, and the network administrator for your company needs your help. The company has just absorbed another small company with five employees. The employees will be moving into your building, and the new network must be able to accommodate the employees. The need to keep the new employees on their own network arises from the inability to completely trust their hardware. New hardware has been ordered, but until it is received and properly set up, there is a need to have the acquired network communicate with the current network.

Current Configuration

Your current network is broken into two separate segments.

The first segment (Subnet1) consists of the following:

- Three personal computers
- One printer
- Class C network
- One switch

The second segment (Subnet2) consists of the following:

- Five personal computers
- One printer
- Class C network
- One switch

The networks are connected to the following:

- Two routers
- One server

The acquired company network (Network3) consists of the following:

- Five personal computers
- One printer
- Class C network
- One switch
- One server

The following are the minimum requirements of the new design:

- New IP configuration that combines Subnet1 and Subnet2 into NetworkA
- Class C network
- Static routing between the NetworkA and Network3
- Configured DHCP services on the server

- NAT configuration on the router for ping capability and communication between all networks
