IT 253 Project Two Overview of Current System

Description

The company's e-commerce system is the most critical element of its business and is comprised of a number of interconnected servers described below. All servers are hosted in the company's main data center.

- A physical Linux web server (WEBSERV01) is running Apache Web Server 2.2 and is currently not placed into a demilitarized zone (DMZ), but there is a firewall (FW1) placed in front of the server. The firewall has been set to its default configurations, and the server is exposed to the internet so that customers can access the website to place orders. Administrators use virtual network computing (VNC) to remotely manage the server from anywhere in the world.
- FW1 has its default configuration in place, and all ports are open.
- SW1 is a layer 3 network switch.
- A virtual database server (DBSERV1) that the web server connects to. DBSERV1 is a virtual server that runs Microsoft Server 2019 and Microsoft SQL 2019. The server is not directly exposed to the internet and is administered by staff with a shared account. The company has decided not to encrypt data.
- A physical enterprise resource planning (ERP1) server is running Microsoft Windows Server 2019. This server processes the orders for the web store and interfaces with other systems in the company's supply chain.

Currently, there is no redundancy configured for all of the servers in the system. Additionally, no server documentation exists other than the network diagram. The servers are not backed up at any regular intervals. You can add equipment as needed as long as you justify the purchases.
